

INST develops oral nanomedicine against kala-azar

24 August 2020 | News

This study by INST team may lead to product and process patent enhancing the role of our country for developing innovative therapy against neglected diseases

Scientists from the Institute of Nano Science & Technology (INST), Mohali have developed an oral nanomedicine with the help of surface-modified solid lipid nanoparticles based combinational cargo system for combating visceral leishmaniasis.

According to the INST team, till-date there is no study reported where a combination of two anti-leishmanial drugs has been delivered through nanomodification as a potential therapeutic strategy against visceral leishmaniasis. This work suggests the superiority of as-prepared modified formulation (m-DDSLNs) surface modified with 2-hydroxypropyl- β -cyclodextrin (HPCD) as a promising approach towards the oral delivery of anti-leishmanial drugs.

In this study by INST team led by Dr. Shyam Lal M anti-leishmanial drugs Amphotericin B (AmB) & Paromomycin (PM) were encapsulated in solid lipid nanoparticles and further modified with 2-hydroxypropyl- β -cyclodextrin (HPCD). The scientists explored the oral therapeutic potential of the formulation in the treatment of visceral leishmaniasis.

They employed an emulsion solvent evaporation method to prepare HPCD modified dual drug-loaded solid lipid nanoparticles (m-DDSLNs). The nanoparticle-based combinatorial drug delivery system developed by them enhanced the efficacy of the formulation in both *in vitro* and *in vivo* models by reducing intracellular amastigote growth in *L. donovani*-infected macrophages and hepatic parasite burden in *L. donovani*-infected BALB/c mice model, respectively without causing any significant toxic side effects.

According to the INST team, the solid lipid nanoparticles (SLNs) can help enhance the oral uptake of the therapeutic agent by retaining a solubilized state of the drug in the Gastrointestinal Tract and favors the formation of mixed micelles (a special case of solubilization) by inducing the secretion of bile salts and phospholipids.

Further, 2-hydroxypropyl- β -cyclodextrin (HPCD) are cyclic oligosaccharides that are known to be molecular hosts which can selectively include water-insoluble guest molecules within their hydrophobic cavity through non-covalent interactions.

This study by INST team may lead to product and process patent enhancing the role of our country for developing innovative therapy against neglected diseases. The usage of lower therapeutic dose of the purified drugs through nanomodifications will be a boon in reducing toxicity, which has been a major hindrance in the existing conventional treatment when administered

orally.
