

Shilpa Medicare opens flow chemistry manufacturing centre in Bengaluru

30 October 2025 | News

Flow Chemistry Centre of Excellence includes more than 100 R&D and manufacturing scientists

Shilpa Medicare, a full-service contract development and manufacturing organization (CDMO), has announced the launch of its new flow chemistry Centre of Excellence (CoE) at CPHI Frankfurt. Based at the CDMO's Bengaluru site, the Centre unites cross-functional teams across R&D and manufacturing to accelerate process development, scale-up, and commercial production for continuous flow.

The new CoE is staffed by a team of more than 100 specialists and integrates Sravathi's proprietary flow technologies with Sravathi's advanced continuous reactor platforms, enabling the development and commercialisation of an expanded range of reactions including fluorination, bromination, nitration, chlorination, oxidation, and Grignard reactions.

Sravathi's flow chemistry group has already developed over 30 flow-based reactions, successfully transferring more than five pilot-scale processes to client sites for commercial manufacture.

In terms of reactors the site features more than 50 patented, custom-designed micro and pilot flow reactors, with lab, bench, and pilot scales ranging from 30 mL/min to 200 mL/min. These systems handle multi-phase, catalytic, and gas-liquid reactions under corrosion-resistant materials of construction, ensuring safety and reliability across highly exothermic or hazardous chemistries. Continuous downstream operations —such as crystallization, extraction, and thin-film evaporation — allow fully integrated end-to-end processing. Designed at Sravathi, the reactors have shown consistent and reliable scale-up from laboratory to commercial operations for processes involving gas-liquid and liquid-liquid reactions. By integrating

scalability considerations into the design, the time-to-market and risks commonly associated with scale-up have been notably reduced.

The centre includes automated processes for temperature and pressure measurements, meaning monitoring and adjustments can be done remotely. This high degree of digitalization ensures reproducibility and scalability while minimizing human intervention during flow operation.
